

NASA-DoD Lead-Free Electronics Project

April 2010

Resources

Project documents, test plans, test reports and other associated information will be available on the web:

- NASA-DoD Lead-Free Electronics Project: <u>http://www.teerm.nasa.gov/projects/NASA_DODLeadFreeElectronics_Proj2.html</u>
 - Joint Test Protocol
 - Project Plan

Project Stakeholders

Test Vehicles

• 193 Test Vehicles Assembled by BAE Systems (Irving, Texas)

120 = "Manufactured"

73 = "Rework"

Circuit Cards

- 14.5"X 9"X 0.09"
- 6 layers of 0.5 ounce copper
- FR4 per IPC-4101/26 with a minimum Tg of 170°C (Isola 370HR)
- Pho-Tronics

NAVSEA Crane Rework Effort

Built 30 test vehicles (sub-set of the 193 assembled)

- Test vehicles were built with Lead-Free solder and Lead-Free component finishes only = similar to Manufactured test vehicles for Mechanical Shock, Vibration and Drop Testing
- Lead-Free alloys, SAC305 and SN100C
- Rework was done using only SnPb solder
- Performed multiple pass rework 1 to 2 times on random Pb-free DIP, TQFP-144, TSOP-50, LCC and QFN components
- Testing
 - Thermal Cycling -55°C to +125°C <u>Testing In-Progress with NASA-DoD</u> test vehicles

 Rockwell

Drop Testing

NSWC Crane Test Vehicles

- Shock parameters: 500 G, 2.0 ms duration (340 G for cards 80, 82, 87 for first
- 10 drops)
- Number of drops: 20
- 9 cards in total / 3 cards tested per drop
- Each card monitored for shock response
- Each card monitored for resistance
- Cards 80, 83, 86 monitored for strain

Drop Testing

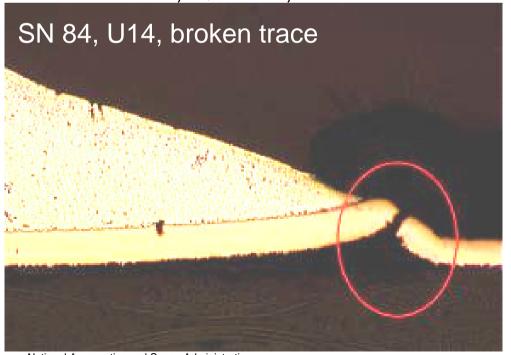

NSWC Crane Test Vehicles

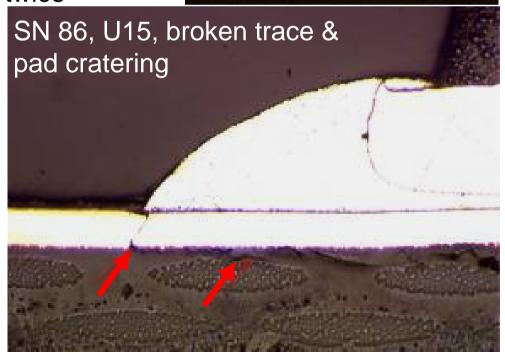

- Only component to have significant failures BGA 225
- The 4 non-BGA samples that had an electrical failure had the

following rework histories:

- SN 85, TQFP 144, U57 was reworked once
- SN 85, PDIP-20, U8 was reworked once
- SN 84, CLCC-20, U14 was not reworked

■ SN 86, QFN-20, U15 was reworked twice

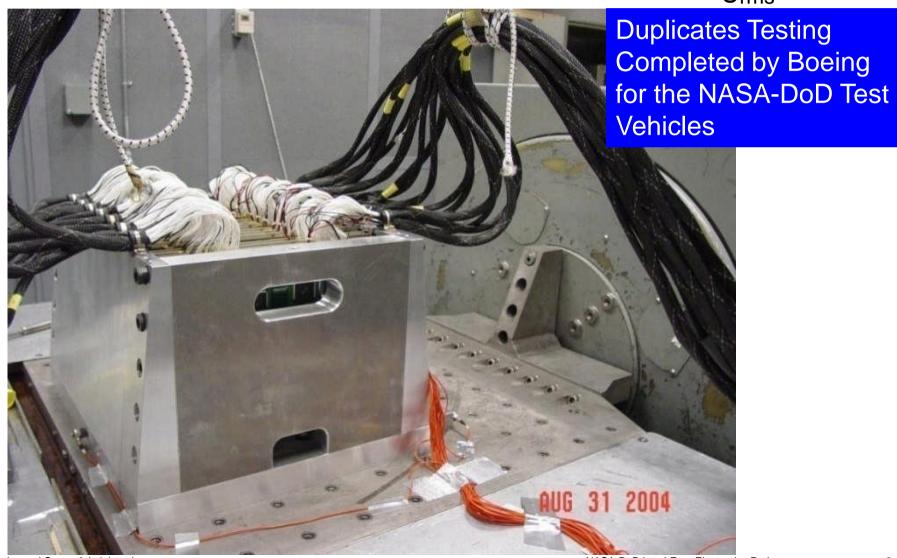

SN 85, U57

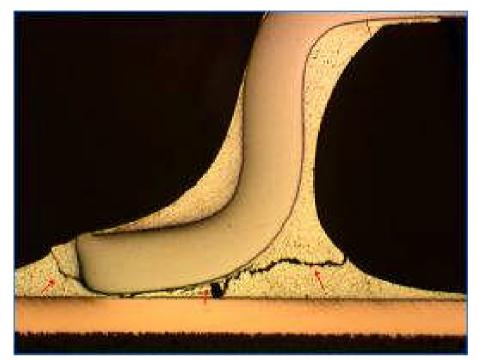

Subject the test vehicles to 8.0 g_{rms} for one hour. Then increase the <u>Z-axis</u> vibration level in 2.0 g_{rms} increments, shaking for one hour per step until the 20.0 g_{rms} level is completed. Then subject the test vehicles to a final one hour of vibration at 28.0 g_{rms} .

- Among the parameters tested, unexplained variation continues to dominate the results
 - Batch or Card S/N did not significantly influence the results
 - Component package style had a marked influence on both the time to failure (Tf) and on the number of cycles to 10% failure (N10)
- Rework
 - Did influence Time to failure
 - Did not significantly influence N10
- Location on the board
 - Did significantly influence Tf
 - Did not significantly influence N10

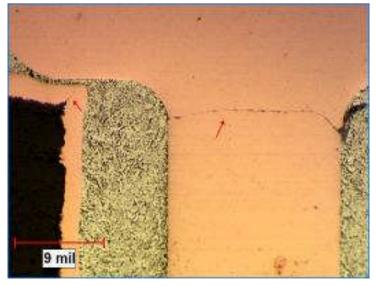

SN67, U61, left lead solder crack, 100x

SN67, U31, left lead solder crack, 100x

SN 79, U49, pin 11, 100x

Testing Activities NASA-DoD Test Vehicles

Specific testing details can be found in the Joint Test Protocol (JTP)

http://www.teerm.nasa.gov/projects/NASA_DODLeadFreeElectronics_Proj2.html

- Thermal Cycle Testing (-20/+80°C) (BOEING*
- Combine Environments Testing Raytheon COMPLETE
- Drop Testing CELESTICA. COMPLETE
- Thermal Cycle Testing (-55/+125°C)
- Vibration Testing (COMPLETE)
- Mechanical Shock Testing COMPLETE

Not Covered in this Presentation

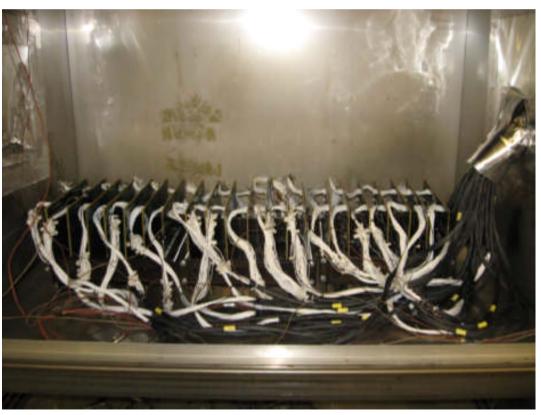

• Interconnect Stress Test (IST) COMPLETE

Thermal Cycle Testing (-20/+80°C)

Test Parameters

- 5 to 10°C/minute ramp
- 30 minute dwell at 80°C
- 10 minute dwell at -20°C

~ 3,000 Thermal Cycles
Completed

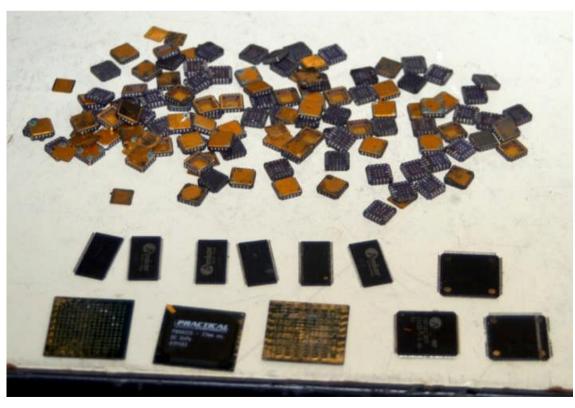

Thermal Cycle with Vibration

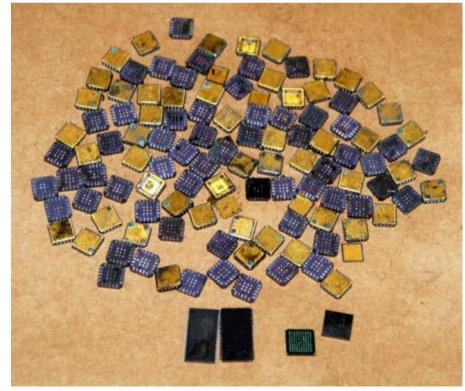

- -55°C to +125°C
- 20°C/minute ramp
- 15 minute dwell at -55°C and +125°C
- Vibration for the duration of the thermal cycle
- 10 g_{rms} pseudo-random vibration initially
- Increase vibration level 5 g_{rms} after every 50 cycles
- 55 g_{rms} maximum

Overall, the component type had the greatest effect on solder joint reliability performance.

- The plated-through-hole components proved to be more reliable than the surface mount technology components.
- The plated-through-holes (PTH), PDIP-20, TQFP-144 and QFN-20 components per-formed the best.
- The BGA-225 components performed the worst.

Solder alloy had a secondary effect on solder joint reliability.

- In general, tin-lead finished components soldered with tin-lead solder paste were the most reliable with the exception of some components with lead contamination in the solder joints.
- In general, tin-silver-copper soldered components were less reliable than the tin-lead solder controls.
- In several cases, tin-silver-copper solder performed statistically as good as or equal to the baseline, eutectic tinlead solder.

In general, reworked components were less reliable than the unreworked components. This is especially true with reworked lead-free CSP-100, reworked lead-free BGA-225

Combine Environments Testing

From this testing, it appears the selection of component type and lead-free solder combinations should be considered critical factors when considering converting to lead-free solder assembly, especially for surface mount technology design configurations.

Manufactured **Test Vehicles**

			1	I		
Board Finish	Component	Finish	Solder	Number of Failed Components

Failure Analysis In-Progress

Failure Analysis Location	Test Vehicle	Component Location	Selection Criteria				
	21	U34	Mfg group - No signal, failed at 0 cycles				
	21	U57	Mfg group - Failed at cycle 1				
	119	U36	Mfg group - Surrounded by components that fell off; failed at 233 cycles				
COM DEV	119	U39	Mfg group - Surrounded by components that fell off; failed at 318 cycle				
	142	U13	Rwk group - Adjacent to rwked components, survived all 650 cycles				
	181	U56	Rwk group - Rwked component failed at cycle 1				
	181	U25	Rwk group - Rwked component failed at cycle 1				
	117	U4	Mfg group - Failed at 20 cycles; SN100C solder paste used				
Lockheed Martin	140	U11	Rwk group - Damaged pad from rwk - Failed at 398 cycles				
	183	U41	Rwk group - Failed at cycle 1, was not rwked				
	23	U30	Mfg group - Survived 650 cycles, surrounded by components that fell off				
Nihon Superior	23	U43	Mfg group - Failed at 120 cycles, located near center of TV				
	72	U29	Mfg group - Location in chamber (low fails); failed at 161 cycles				
	158	U6	Rwk group - Rwked component failed at cycle 1				
	180	U21	Rwk group - Rwked component failed at cycle 1				

Thermal Cycle Testing (-55/+125°C)

Test Parameters

- 5 to 10°C/minute ramp
- 30 minute dwell at 125°C
- 10 minute dwell at -55°C

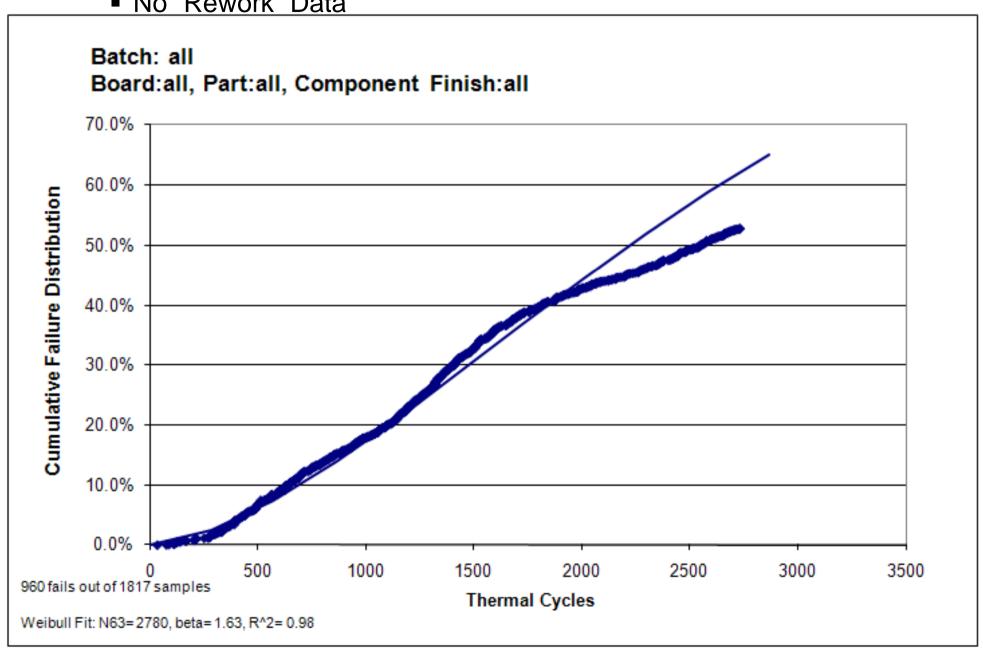

~3,000 Thermal Cycles
Completed

Thermal Cycle Testing (-55/+125°C)

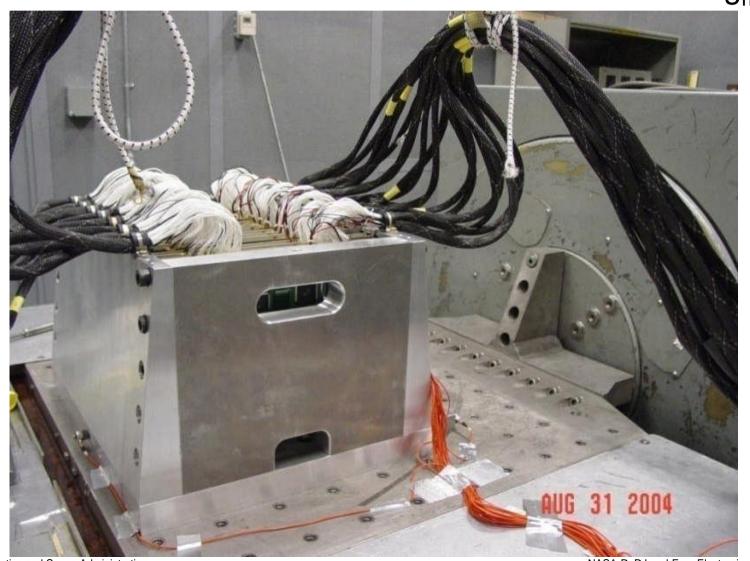

Data Snapshot from "Manufactured" Test Vehicles

No "Rework" Data

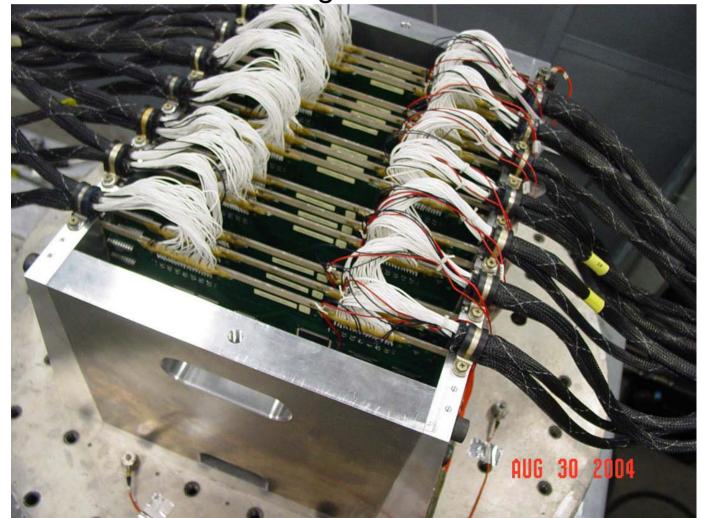

Subject the test vehicles to $8.0\ g_{rms}$ for one hour. Then increase the Z-axis vibration level in 2.0 g_{rms} increments, shaking for one hour per step until the 20.0 g_{rms} level is completed. Then subject the test vehicles to a final one hour of vibration at 28.0 g_{rms} .

- Very early PDIP failures were observed.
- At an initial glance, the data does not look much different than the JCAA/JGPP test results.
- There does seem to be a big difference between solder alloys.

- Additional Failure Analysis Efforts are Needed
 - Need In-Kind Contributions or Direct Funding
 - In-Kind Failure Analysis Providers Completing 5 to 10 Cross Sections per Location
 - You can have as many as you want!

Mechanical Shock Testing (APOEING)

Project representatives felt that only testing in the Z-axis was required as this is the only axis which allows significant board bending and subsequent solder joint failures.

ig and subsequent solder joint failures.							
Parameters	The shock transients will be applied perpendicular to the plane of the board and will be increased after every 100 shocks (i.e., a step stress						
	test). For Level 6 (300 G's), 400 shocks will be applied. Frequency						
	1	,	* *			applied. r	requency
	range is 40 to 1000 Hz. SRS damping: 5%						
	Test Shock Response Spectra			Ampl	itude	Te	Shocks per
				(G	's)	(msec)	Level

Mechanical Shock Testing (POEING:

In general SAC305 performed as well as the SnPb for surface

ount components.	% of Components Failed During Mechanical Shock Testing					
		actured" ehicles	"Rework" Test Vehicles			
	SnPb	Pb-Free	SnPb	Pb-Free		
Component						
BGA-225	94	96	95	100		
CLCC-20	22	30	22	30		
CSP-100	32	26	42	38		
PDIP-20	53	73	54	58		
QFN-20	0	10	0	0		
TQFP-144	70	62	68	80		
TSOP-50	4	0	22	20		

Mechanical Shock Testing (ABOEING)

- The very first components to fail were lead-free PDIP components
 - Lead cracking in the fillet area is being observed as well as some trace cracking near the corner leads. It is not possible to determine if one event happened before the other or if the events are happening simultaneously.
- All of the test vehicles passed the first 3 levels of testing which were conducted per MIL-STD-810F, Method 516.5; Modified Functional Test for Flight Equipment (Level 1), Modified Functional Test for Ground Equipment (Level 2), and Modified Crash Hazard Test for Ground Equipment (Level 3).
 - 100 shocks were conducted in the z-axis for each of the three levels, equating to conducting each of the three tests 33 times.
- It appears that the predominant failure mechanism for the BGA components was pad cratering no matter the solder alloy; leadfree or SnPb.

Mechanical Shock Testing (ABOEING)

- Additional Failure Analysis Efforts are Needed
 - Need In-Kind Contributions or Direct Funding
 - In-Kind Failure Analysis Providers Completing 5 to 10 Cross Sections per Location
 - You can have as many as you want!

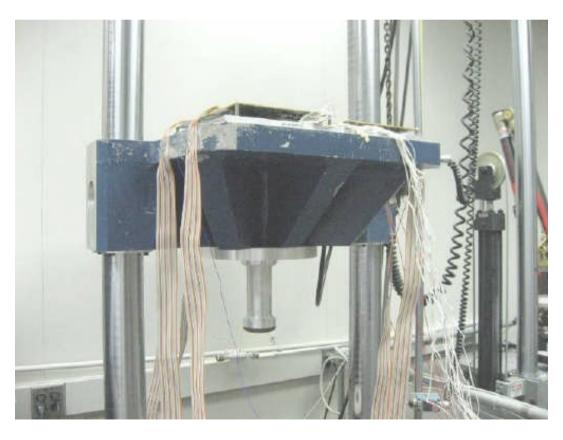

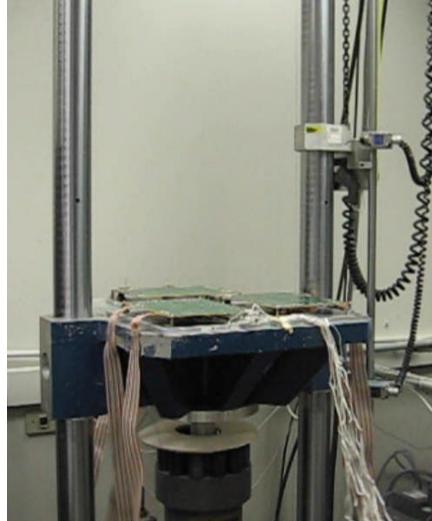

NASA-DoD Test Vehicles

- Shock testing will be conducted in the Z axis
- 500Gpk input, 2ms pulse duration

• Test vehicles will be dropped until all monitored components fail

or 10 drops have been completed

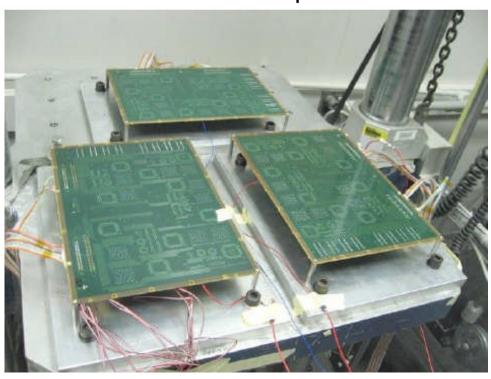

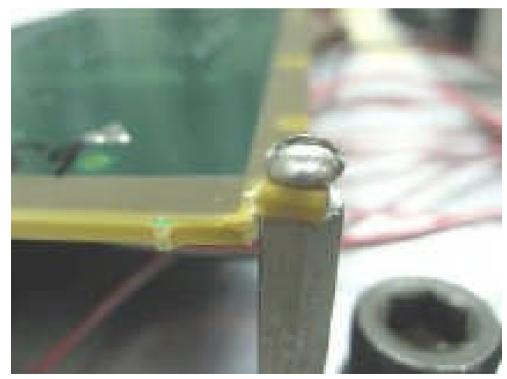

Drop Testing

NASA-DoD Test Vehicles

- Only component to have significant failures BGA 225
- Most failures occurred on or near the corners.
- General ranking Based on Raw Data No Failure Analysis
 - Overall; Manufactured test vehicles performed better than Rework test vehicles
 - SnPb Manufactured performed better than Lead-Free Manufactured
 - SnPb Reworked performed better than Lead-Free Reworked

- Failure Analysis Efforts are Unfunded
 - **Need In-Kind Contributions or Direct Funding**
 - In-Kind Failure Analysis Providers Completing 5 to 10 Cross Sections per Location
 - You can have as many as you want!
